ing-age population ratio are almost identical. If anything, aging is even more rapidly progressing in Korea, in the sense that Korea's working-age population ratio is decreasing faster and Korea's old dependency ratio is increase faster than Japan's corresponding ratios.

Figure 6 shows Japan's actual and fitted growth rates. The actual growth rate is a five-year moving average (from t-5 to t). The model explains the movements of Japan's growth rates quite successfully except for the recent few years. The model actually predicts lower than actual growth rates in the most recent years. For example, the predicted growth rate in 2013 is - 1.6% while the actual growth rate is 0.4%. This may reflect the possibility that Japanese policies not captured by the model helped mitigate the effect of aging on growth.

Figure 7 shows the actual, fitted and future projections of Korea's growth rates. There is approximately a twenty year demographic gap between Korea and Japan. Therefore, in order to compare projections of Korea's future growth rates with Japan's past performance, we projected Korea's future growth rates up to twenty years. The future predicted values of demographi-

¹¹ The estimated coefficients in Column 2 in Table 2 are used to predict growth rates, as young and old dependency ratios are used for future projections later. However, predictions based on the other estimated coefficients do not vary much.

cal variables such as population and young and old dependency ratios were collected from Statistics Korea. Since there is some discrepancy in actual values of demographical variables between WDI and Statistics Korea, we adjusted future predicted demographic variables by equating the two values in 2014. We also assumed that there is no further change in human capital, but that openness and capital changes at the same rate as the average of the past 10 years.

The fitted growth rates also mimic Korea's actual growth rates quite well. However, the projected growth rates decline continuously, to reach -2.7% in 2034, implying that Korea's

growth rate in 2034 will be even lower than Japan's fitted growth rate from 20 years ago, which is -1.6%. One possible explanation is that, as we already explained above, aging is progressing even more rapidly in Korea than it did in Japan. Korea's future may thus be even gloomier than Japan's present.

6. Policy implications for Korea (and Japan)

In this section, we explore the policy implications of Korea's rapid population aging and its negative impact on growth.

6. 1. Past policy responses of Korea

Concerned about population growth and overpopulation, the Korean government kicked off a family planning program in 1962. [Lee and Choi (2015)] By 1996, the pendulum had swung the other way and fertility rate collapsed to well below replacement levels. As a result, the government eliminated its family planning program and instead put into place a series of pro-fertility programs aimed at tackling population aging. In addition, the government sought to tackle female infanticide, the related problem of unbalanced ratio of births, and reproductive health.

A significant law, the Framework Act on Low Birth Rates in an Aging Society, was enacted in 2005, and a presidential committee was set up the same year. The Act created the first Basic Plan for Low Fertility and Aging Society for 2006 to 2010. [Lee *et al.* (2013b)] The five-year plan, which seeks to boost fertility and address population aging, was renewed in 2011 and again in 2016. The plan's results are evaluated every year by the national parliament and government, and those evaluations inform and guide the formulation of the action plan for the following year. Broadly speaking, the government's efforts to increase fertility is based on three strategies. [Lee *et al.* (2013b)] First, the government seeks to strengthen support for childbirth and child rearing. Second, the government aims to foster a culture and society which protects the family and treats men and women friendly. Third, the government hopes to expand investment in the health of future generations.

With respect to childbirth and child rearing, the Korean government provides fees for care and kindergarten or, alternatively, allowance for childcare at home. It also provides free after-school education programs. Families with children receive other financial support, including more favorable tax treatment and means-tested loans program for home purchase or

renting. In addition, the government delivers pre-natal and post-natal health care and subsidizes the costs of in-vitro fertilization.

Realizing the vital importance of work-life balance for child birth and child care, the government tries to help parents balance work and family. [Lee and Choi (2015)] More specifically, the government mandates 90 days of maternity leave at 100% of salary and one year of childcare leave at 40% of salary, up to a maximum of 1,000,000 Korean won (around US\$900) per month. Furthermore, male workers are granted 5 days of parental leave, 3 days at 100% of salary and 2 days unpaid, when their wives give birth. Female workers are entitled to return to their for positions after their maternity or childcare leave. The penalty for employers who break the rules is a heavy fine of up to 5,000,000 Korean won (around US\$4,500).

Another set of government policies to boost fertility is centered on creating more family-friendly working conditions. [Lee and Choi (2015)] In this context, the Korean government is expanding workplace daycare centers, reducing work hours, and encouraging more flexible working conditions. It has also launched public education campaigns to foster gender equality within families and the society at large, in addition to publicizing and rewarding family-friendly companies with a certificate containing a special logo. An emphasis on the health of infants and children is an integral part of the Korean government's strategic response to excessively low fertility levels and demographic change toward older populations [Lee (2015)].

In addition to pursuing various pro-natalist policies to reverse or at least slow down population aging, the Korean government must cater to the needs of the country's large and fast-growing elderly population. [Park *et al.* (2012)] In this connection, it has taken action to promote the economic security, healthcare, and well-being the elderly. Economic security-enhancing policies include promoting more employment opportunities for the elderly, providing assistance for job training and retraining, and supporting elderly entreprenueurs starting new businesses. At the same time, the government is enhancing public and private pension systems, and has introduced a new basic old age pension which covers the majority of the elderly population. More and better employment opportunities will help the elderly remain valuable members of society, rather than become just social security beneficiaries.

Since elderly health care can be very costly, old-age economic security must be accompanied by a good health care system for the elderly. In this connection, the Korean government is making concerted efforts to set up a a preventive care system, stabilize medical costs, and improve health insurance coverage. [Park *et al.* (2012)] Other policy measures include (i) providing greater opportunities for volunteer work and leisure activities, (ii) improving housing, transportation, and other social infrastructure for the elderly, and (iii) building up a more

robust social protection system which minimizes the risk of being abused for the vulnerable elderly, such as those who live alone. In addition, the government has launched various campaigns aimed at encouraging a more active lifestyle among the elderly. Leading more active lives, for example by engaging in sports and other high-energy activities, not only contributes to better health but also directly improves the well-being of the elderly.

6.2. Future policy options for Korea

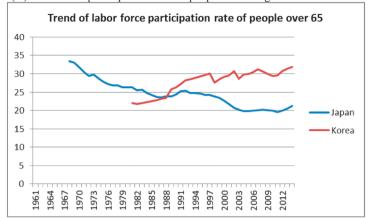

The previous section indicates that the Korean government is actively pursuing a wide range of policy measures to address the problem of rapid population aging. Many of those measures are aimed at raising fertility and some measures are designed to help Korea's elderly population. Despite growing government activism, Korea's rapid population aging shows no signs of slowing down, let alone reversing, as shown in Figure 3A. Therefore, going forward, Korean policymakers must give serious consideration to experimenting with different policy directions. While one broad direction is to pursue existing policies more effectively for greater impact, another strategy is to think outside the box and boldly try completely new policies.

The existing set of government policies can be improved through better implementation and more systematic coordination. For example, a holistic approach is required to raise the participation of married women in the workforce. The experiences of France and Sweden, two rare examples of countries where government intervention seems to have had a tangible effect in arresting a decline in fertility, suggest the pivotal importance of creating a flexible and friendly work environment which enables women to balance work and family. [Lee *et al.* (2009)] While Korea has bits and pieces of such a pro-family environment, those bits and pieces are not integrated into a systematic policy regime. As a result, the Korean work environment has a long way to go from fully welcoming the participation of female workers. This explains why Korea still has one of the lowest female labor force participation rates in OECD, along with Japan, even though it has been increasing continuously, as illustrated in Figure 8A. This is particularly important because higher female labor force participation rate is associated with faster economic growth, as we found empirically in Section 4. However, this may result in lower fertility rate, pointing to a need for a set of carefully calibrated policies that enable women to work *and* have and raise children.

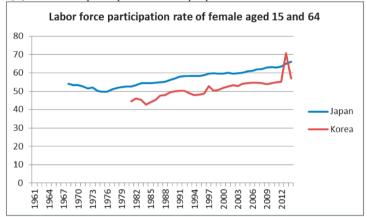

Figure 8B also illustrates that the labor force participation rate of the elderly in Korea has been continuously increasing, while that in Japan has been decreasing. It was found empirically in Section 4 that a higher labor participation of the elderly does not positively contribute to

Figure 8. Trend of labor force participation rates of female aged 15 and 64 and people over 65

(A)Labor force participation rates of people female aged 15 and 64.

(B) Labor force participation rates of people over 65

Data Source: International Labor Organization's online database (ILOSTAT).

economic growth. This might seem to weaken the case for policy support for elderly work, but there are other important factors at play. In particular, many elderly Koreans are forced to work at old age because they do not have adequate retirement income. [Park *et al.* (2012)] The national pension system was set up only in 1988, and extensive social, economic and cultural changes have weakened intra-family support. Therefore, until the pension and retirement system becomes more well-established, enabling the elderly to find work — for example, by introducing more flexible wage systems that allow the elderly to work less for lower pay — will remain a vital part of old-age income security in Korea.

Overall, there is a need for different government agencies to work systematically together,

perhaps under a high-level National Aging Council. Such a council can take a holistic view of Korea's aging challenge and enable the government to formulate and implement a strategic and systematic policy response, taking into account the views of all stakeholders. Furthermore, in light of the clear and present threat that rapid population aging poses to Korean economy and society, there is a growing case for Korean policymakers to think outside the box. More liberal and systematic immigration policy regime is a clear example of thinking outside the box [Lee (2015)]. As an ethnically and culturally homogeneous people, Koreans can be inward-looking and unwelcoming to foreigners. Moreover, in the past, low income level meant that Korea was a source of emigration to other countries rather than a destination for immigrants from other countries. However, more recently, the economic miracle which transformed the country into one of Asia's richest economies has transformed the country from a source of emigration to a destination for immigration. There is thus a strong win-win economic case for encouraging immigration from poorer and younger Asian countries. The experience of Singapore underlines the potential economic benefits of immigration.

On top of that, a rising proportion of Koreans are marrying foreigners, giving rise to a sizable multicultural population. This trend may even change the meaning of what it means to be Korean. While foreign immigrants have become a fact of life and Korean governments have made efforts to integrate them into national life, much more can be done to make immigration an integral part of the solution to population aging. For example, perhaps because immigration is a relatively new phenomenon, Korea does not have a clear and systematic immigration strategy for attracting and retraining the kinds of immigrants that would yield the greatest benefits for the economy and society.

7. Summary and concluding remarks

Without a doubt, population aging is one of the most significant structural challenges facing the world economy. The visible slowdown of economic growth across the world since the global financial crisis probably reflects both cyclical and structural factors. Yet the persistence of the slowdown and the apparent inability of the world economy to stage a sustainable recovery, and the constant downgrading of global growth forecasts by the IMF and other organizations, is giving rise to concerns that the deceleration is primarily structural rather than cyclical. The secular stagnation hypothesis is one well-known example of such concerns and pessimism. One structural driver of the global slowdown which is highlighted by many experts is the worldwide demographic transition to older population structures. The transition is most ad-

vanced in high income countries, but is also evident in many middle income countries, most notably China. In principle, population aging adversely affects growth through a number of channels, in particular its adverse effect on labor supply.

However, notwithstanding the intuitively and theoretical rationales for a negative impact of older demographic profiles on economic performance, the link between demographics and growth is ultimately an empirical issue. The central objective of our paper is to take a more indepth look at the demographics-growth nexus by performing rigorous econometric analysis on panel data. Our panel data analysis yields some interesting and significant findings. Above all, our empirical evidence confirms the harmful effect of population aging on economic growth in both short run and long run. We also find that elderly participation in labor force has a positive influence on economic growth, which suggests that the harmful effect of aging can be mitigated by more active participation of the elderly in the labor force. Finally, we find that the future level of population aging, not just the past level, has a detrimental effect on economic growth. Future aging may raise concerns about future growth prospects and thus adversely affect current economic activity.
